ABSTRACT

Cationic rhodium(I)/modified BINAP complexes are effective catalysts for highly regioselective intermolecular cyclotrimerization of terminal alkynes and highly chemo- and regioselective intermolecular cocyclotrimerization of diethyl acetylenedicarboxylate (DEAD) and terminal alkynes. It is a noteworthy example of intermolecular cocyclotrimerization of two different alkynes in terms of catalytic activity, chemo- and regioselectivity, scope of substrates, and ease of operation. The wide applicability of this new cocyclotrimerization procedure is demonstrated in the one-step synthesis of [6]metacyclophane.

Highly regiocontrolled synthesis of arenes is attractive because arenes are important building blocks in organic synthesis. Cyclotrimerization of alkynes to yield substituted benzenes is a possible method for their synthesis. Although various transition metals catalyze alkyne cyclotrimerization, it has been difficult to carry out that intermolecular reaction in a highly regioselective manner. In particular, catalytic chemo- and regioselective intermolecular cocyclotrimerization of two different alkynes has not been established yet.

In general, a partially intramolecular reaction between an α,ω-diyne and excess mononoyne and a completely intramolecular reaction have been employed to overcome this problem. The present study describes highly regioselective intermolecular cyclotrimerization of terminal alkynes and highly chemo- and regioselective intermolecular cocyclotrimerization of diethyl acetylenedicarboxylate (DEAD) and terminal alkynes catalyzed by cationic rhodium(I)/modified BINAP complexes (Figure 1).

Although a neutral rhodium(I) complex is an effective catalyst for partial or complete intramolecular cyclotrimerization, the present study is the first example of such a reaction using a cationic rhodium(I) complex. The catalytic system consists of a cationic rhodium(I) complex and a modified BINAP ligand, which is bis(4-methylacetophenone)modified BINAP (BIM-BINAP). The modified BINAP ligand is more effective than the neutral BINAP ligand in promoting the intermolecular cyclotrimerization of terminal alkynes.

The present study describes a highly regioselective intermolecular cyclotrimerization of terminal alkynes and highly chemo- and regioselective intermolecular cocyclotrimerization of diethyl acetylenedicarboxylate (DEAD) and terminal alkynes catalyzed by cationic rhodium(I)/modified BINAP complexes (Figure 1).

Figure 1. Structures of modified BINAP ligands.
application of a cationic rhodium(I) complex in oligomerization of terminal alkynes remains unexplored.\(^{11}\)

We examined the reaction of 1-dodecyne (1a) first using 5 mol% of [Rh(cod)\(\text{BF}_4\)]/10 mol% PPh\(_3\) at room temperature. The reaction was very slow, but a small amount of cyclotrimerization products was detected (Table 1, entry 1). Although the use of various monodentate or bidentate phosphine ligands (PPh\(_3\), n-BuP, dppe, and dcppe) furnished cyclotrimerization products, the catalytic activities were low (entries 1–4).

(2) Ni(0)-catalyzed cyclotrimerization of methyl propiolate and terminal alkynes was reported. Although the regioselectivity is high, chemoselectivity is moderate, and the reaction requires slow addition of methyl propiolate ((over 5–60 min) and a substoichiometric amount of zinc(II) phenoxide: Mori, N.; Ikeda, S.-I.; Odashima, K. Chem. Commun. 2001, 181–182.

(4) Palladacyclopentadiene-mediated cyclotrimerization of two molecules of dimethyl acetylenedicarboxylate and one molecule of diphenylacetylene was reported (76% yield), but this reaction proceeded in low yield (40% yield) under catalytic conditions (regioselectivity is not relevant to this case): Dieck, H. T.; Munz, C.; Müller, C. J. Organomet. Chem. 1990, 384, 243–255.

(8) Surprisingly, the use of Tol-BINAP dramatically improved catalytic activity and cyclotrimerization products were obtained in almost quantitative yield with moderate regioselectivity (entry 5). The use of cationic Rh(I) complex is essential for this reaction. The use of neutral Rh(I)/Tol-BINAP complex or cationic Ir(I)/Tol-BINAP significantly decreased the activity (entries 6 and 7). Both high activity and regioselectivity were achieved by use of the cationic Rh(I)/H8-BINAP complex. Both non-conjugated (1a) and conjugated (1b) terminal alkynes were good substrates yielding 1,2,4-trisubstituted benzenes 2 in high yield with high regioselectivity (entries 8 and 9).

Next, we investigated intermolecular cocyclotrimerization of two different alkynes. After screening various alkynes and cationic Rh(I)/modified BINAP complexes, we found that the cationic Rh(I)/H8-BINAP complex catalyzed chemoselectively intermolecular cocyclotrimerization of DEAD (4) and terminal alkynes. Table 2 shows that two molecules of 1 cleanly reacted with one molecule of 4 to yield 3,6-disubstituted diethyl phthalate 5 in high yield with high regioselectivity upon treatment with catalytic amount of cationic Rh(I)/H8-BINAP complex.\(^{13}\) Alkyl- (1a, entry 1), chloroalkyl- (1c, entry 2), methoxymethyl- (1d, entry 3), aryl- (1e, entry 4 and 1f, entry 5), and alkynyl-substituted (1b, entry 6) terminal alkynes were suitable substrates for this reaction. Although the reaction of sterically demanding trimethylsilylacetylene (1g) furnished 5g in moderate yield, excellent regioselectivity of 5g was observed (entry 7).

\(^{a}\) Rh or Ir complex (0.005 mmol), phosphine (0.005 or 0.01 mmol), 1-dodecylne (0.1 mmol), and CH\(_2\)Cl\(_2\) (1 mL) were employed. \(^{b}\) The active catalysts were prepared by mixing Rh or Ir complex and phosphine in CH\(_2\)Cl\(_2\) followed by hydrogenation (1 atm, rt, 0.5 h). \(^{\dagger}\) Determined by \(^1\)H NMR. \(^{\ddagger}\) Isolated yield. \(^{\S}\) Reaction time = 24 h.

Scheme 2 depicts a plausible mechanism of this cationic rhodium(I)/H8-BINAP complex-catalyzed intermolecular cocyclotrimerization. Chemo- and regioselectivity is determined by preferential formation of metallacycle A instead of C and D followed by the coordination of terminal alkyne to form complex B.\(^{15}\) Reductive elimination of rhodium gives 5 and regenerates the rhodium catalyst.

The wide applicability of this new cocyclotrimerization procedure is demonstrated in the synthesis of metacyclophane (Scheme 3). The reaction of commercially available 1,9-decadiyne (8) and 4 gave a [6]metacyclophane 9 in 50% yield. This is the shortest (one-step) synthesis of a metacyclophane starting from commercially available reagents.\(^{16}\)

In conclusion, we discovered that cationic rhodium(I)/modified BINAP complexes are versatile new catalysts for highly regioselective intermolecular cyclotrimerization of terminal alkyne, and highly chemo- and regioselective intermolecular cocyclotrimerization of DEAD and terminal alkyne. This catalyst system is the first example of efficient rhodium(I)-catalyzed intermolecular cyclotrimerization of terminal alkyne. It is a noteworthy example of intermolecular cocyclotrimerization of two different alkyne in terms of catalytic activity, chemo- and regioselectivity, scope of substrates, and ease of operation. Work toward developing an asymmetric variant of this process is underway and will be reported in due course.

\(^{15}\) The use of rhodium(I)/DTBM-SEGPHOS complex for the cocyclotrimerization of 1 and 4 significantly lowered the yield of 5 as a result of the generation of 2 and 3 as byproducts. The use of rhodium(I)/Tol-BINAP complex significantly decreased the regioselectivity of 5.
